Fuzzy Subtarctive Clustering, Hamming, Minkowski Chebysev Abstract: Clustering is a fita analysis process which applied to classify the unlabeled data. Fuzzy clustering is a clustering method based on membership value which enclosing set of fuzzy as a measurement base for classification process. Fuzzy Subtractive Clustering (FSC) is included in one of fuzzy clustering method. This research applies Hamming distance and Minkowski Chebisev combination listance as a distance parameter in Fuzzy Subtractive Clustering. The objective of fix research is to compare the output quality of the cluster from Fuzzy Subtractive Clustering by using Hamming distance and Minkowski Chebisev combination distance and Minkowski Chebisev combination distance. This research shows that the Partition Coefficient value resulted on Fuzzy Subtractive Clustering by applying Minkowski Chebisev distance. This concludes that the output quality of the cluster by using Minkowski Chebisev distance is better.

1. INTRODUCTION

Clustering is a data analysis process which applied to classify the unlabeled data (Gan et al., 2007). In the optimum classification, each set of data will have a high percentage of similarity on certain cluster. Principally, cluster analysis will classify the given set of data which have high similarity into the same cluster and the dissimilar set of data into different cluster (Rencher, 2016).

Fuzzy clustering is a clustering method which applied to determine the set of data into certain cluster based on their membership value (Sharma & Verma, 2019). There are no certainty on each data to be included in one certain cluster. Hence, each data will have the possibility to be included as a member in different cluster (Jang et al., 2005). There are few known method for fuzzy clustering process, which are Fuzzy C-Means method and Fuzzy Subtractive Clustering.

Fuzzy Subtractive Clustering is one of the clustering method where the number of cluster classification is still undetermined yet. The basic concept of this method is to establish the coordinate of each data which possess the highest number of density value. Set of coordinate which have the highest number of neighboring coordinates will be chosen as the cluster centroid and its density values will get reduced (Sangadji et al., 2018). In this method, the obtained number of cluster are affected by certain parameter, which is the radius (Dyvak et al., 2018).

Few researches has been done by applying Fuzzy Subtractive Clustering, such as the research which done by (Ghane'i Ostad et al., 2018) to determine the overlapped community on LBSN. In this research, every cluster centroid will be defined by the application of buzzy Subtracting Clustering based on each set of data potentials. This research concludes that the given method have higher accuracy than the previous used method.

The research which analyzed by (Salah et al., 2019) is applying subtractive classification which combined with swam particle optimization based on fuzzy classifier. Furthermore, (Abdolkarimi & Mosavi, 2020) also do a research related with fuzzy inference system for subtractive clustering which combined with wavelet for improving the navigation system. Other than that, (Banteng et al., 2019) and (Zeng et al., 2019) also applying subtractive clustering to analyze ad hoc cellular network based on information criteria for forecast process based on linear combination with independent variables.

Another research also worked by (Benmouiza & Cheknane, 2019) with the objective to forecast the solar radiation value by applying subtractive clustering, fuzzy c-means, and network partition. Three clustering methods used in this research is done for classifying every given set of data into certain classification so that each data included on certain signification have the high percentage of similarity to improve the understanding of the correlation between each data and to simplify the forecasting process.

In Fuzzy Subtractive Clustering method, the similarity measurement to determine the number of points which have the highest number of neighboring points is needed. The most frequently used distance parameter to determine the similarity measurement is Euclidean distance. In (Rezaei & Rezaei, 2019), the most known distance measurement to measure the distance between two set of fuzzy clusters is Hamming distance. This statement became the basis on the application of Hamming distance for this research. Other than the Hamming distance, the Minkowski Chebisev combination distance application also had been analyzed by (Rodrigues, 2018) for classifying process by using K-Nearest Neighbors (KNN) and (Surono & Putri, 2020) for clustering with Fuzzy C-Means and Principal Component Analysis application. Based on the statement below, this research will compare the achieved result through the application of Hamming distance and Minkowski Chebisev combination distance for clustering method.

2. **I**ITERATURE REVIEW

2.1. Fuzzy Subtractive Clustering

Fuzzy clustering is a clustering method based on the membership values which enclose fuzzy cluster as a clustering measurement basis. Every set of data are provided with probability value for their classification into existing group, this means that this each of data is not absolutely included in only one cluster and they will have a probability value to be classified in different cluster which have the highest percentage of membership level.

Fuzzy Subtractive Clustering (FSC) is one of the fuzzy clustering method where the number of existing cluster is unestablished yet. The basic concept of this method is to determine every coordinates of each data which have the highest density with their neighboring points. The coordinate with the highest number of neighboring points will be used as the cluster centroid. Then, the density level of the coordinate which used as a cluster centroid will be reduced and algorithm will determine the different coordinates which have the highest number of neighboring points to become another cluster centroid. This process will be executed until every set of coordinates have been tested.

3. **RESEARCH METHODS**

3.1. Fuzzy Subtractive Clustering Steps

The method used in this research is Fuzzy Subtractive Clustering (FSC) with distance parameters, namely Hamming distance and Minkowski Chebisev combination distance. The obtained flusters will be evaluated using the Partition Coefficient to see the quality of the clusters. The data used in this study is hypertension patient data. The variables used were age (X_1) , gender (X_2) , systolic pressure (X_3) , diastolic pressure (X_4) , and body weight (X_2) . Information about the methods used in this study will be described as follows:

- a. Determine the parameter values, which are, r (radius), q (squash factor), accept ratio, reject ratio.
- b. Transform the given set of data into fuzzy number by applying membership function (Mahajan & Gupta, 2019) (Debnath & Gupta, 2019):

$$\mu(x) = \begin{cases} 1 & x \le a \\ \frac{e^{-\left(\frac{x-a}{b-a}\right)} - e^{-s}}{1 - e^{-s}} & a \le x \le b \\ 0 & x \ge b \end{cases}$$
(1)

c. Determine the potential of every given set of data D_i ; i = 1,2,3, ..., n with steps as follows:

First, measure the distance for every given set of data by applying: Hamming distance (Chen & Deng, 2020)

$$Dist_{ij} = \left(\frac{|\mu_A(u_i) - \mu_B(u_i)|}{r}\right)$$
(2)

Minkowski Chebisev combination distance (Rodrigues, 2018) :

$$Dist_{ij} = \left(\frac{w_1 \sqrt[p]{\sum_{m=1}^k |x_m - y_m|^p} + w_2 max_{m=1}^k |x_m - y_m|}{r}\right)$$
(3)

Second, determine the initial potential of each data by applying:

$$D_{i} = \sum_{k=1}^{n} e^{-4\left(\sum_{j=1}^{m} Dist_{ij}^{2}(x_{i})\right)}$$
(4)

d. Find the data coordinates with the highest level of potential:

 $M = max[D_i | i = 1, 2, ...,]$; for the first iteartion.

 $Z = max[D_i|i = 1, 2, ...,]$; for the second, thord, and the following iteration.

e. Measure the ratio (R) of the cluster centroid candidates by applying the following equation:

$$R = \frac{Z}{M}$$
(5)

In initial iteration, value Z=M.

f. Theck the suitability of the cluster centroid candidates to become the cluster centroid by using 3 condition as follows:

Condition 1: If ratio > accept ratio, the cluster centroid candidates are suitable to become the cluster centroid.

Condition 2: If reject ratio < ratio \leq accept ratio, further suitability test will be executed to determine whether the cluster centroid candidates are suitable to become the new cluster centroid. If the result of suitability test still below the minimum requirement for cluster centroid suitability value, the iteration process will be terminated because there are no further data available for further consideration. The steps for executing the second condition process are:

$$Md = -1$$

for k = 1,2, ..., p, where p= the number of cluster.

 $Sd_{k} = \sum_{j=1}^{m} \left(\frac{V_{j} - C_{kj}}{r}\right)^{2}$ If (Md < 0) or $(Sd_{k} < Md)$, then $Md = Sd_{k}$, (6)

$$Mds = \sqrt{Md}$$

Where Mds is the nearest distance between the coordinates of the cluster centroid candidates to the cluster centroid. If $(ratio + Mds) \ge 1$; the cluster centroid candidates are suitable to become the new cluster centroid. Meanwhile, if (ratio + Mds) < 1; then, the cluster centroid candidates are not suitable and won't be reconsidered as the new cluster centroid (potential of the data is set to 0)

Condition 3: if ratio \leq reject ratio, there will be no further data consideration to become the cluster centroid candidates and the iteration process will be terminated.

g. If the new cluster centroid has already acquired, the data potential around the existing cluster centroid will be reduced by using equation:

$$D_i^t = D_i^{t-1} - D_{c_{ki}} (7)$$

where

$$D_{c_{ki}} = Z * e^{-4 \left[\sum_{j=1}^{m} \left(\frac{C_{kj} - x_{ij}}{r * q} \right)^2 \right]}$$
(8)

h. Retransform the cluster centroid into the its data original form:

$$x = (a - b)\ln(\mu - \mu e^{-s} + e^{-s}) + a$$
(9)

i. Measure the membership degree by using equation:

$$\mu_{k_i} = e^{-\sum_{j=1}^m \left(\frac{x_{ij} - c_{kj}}{\sqrt{2}\sigma_j}\right)} \tag{10}$$

where

$$\sigma_j = \frac{r * \left(X_{max_j} - X_{min_j} \right)}{\sqrt{8}} \tag{11}$$

j. Determine the validity index by applying Partition Coefficient (Utomo & Marutho, 2018)

Nama penulis pertama (Judul Singkat)

$$PC = \frac{1}{N} \left(\sum_{i=1}^{N} \sum_{j=1}^{K} \mu_{ij}^{2} \right)$$
(12)

with N is the number of research object, K is the number of cluster, and μ_{ij} is the membership value of the object "I" on cluster centroid "j".

4. RESULT AND DISCUSSION

FSC measurement process will resulting in number of acquired cluster and Pasition Coefficient value. The parameter value which applied in this research are q = 1.25, accept ratio = 0.8, reject ratio = 0.2, r = 0.72, 0.79, 0.97, 1.12, 1.31, and 1.6. Data which used for FSC measurement will be transformed into fuzzy number by applying equation (1) with the result as follows

| | Table 1 Fu | zzy Numbers | | |
|--------|-----------------------|-----------------------|--------|----------------|
| X1 | <i>X</i> ₂ | <i>X</i> ₃ | X_4 | X ₅ |
| 0 | 0 | 0.4609 | 0.1289 | 0.4018 |
| 0.3913 | 1 | 0.5516 | 0.4785 | 0.1468 |
| : | : | : | : | : |
| 0.5734 | 0 | 0.3775 | 0.2862 | 0.6813 |

Furthermore, clustering by using Hamming distance for each existing radius will resulted in 3 classification; by using r = 0.72, 4 clusters will be achieved; by using r = 0.79, 3 clusters will be achieved; and by using r = 0.97, 2 clusters will be achieved. The achieved cluster centroid are described as follows:

$$\begin{split} C_{0.72} &= \begin{bmatrix} 0.4340 & 0 & 0.4609 & 0.2862 & 0.4018 \\ 0.4634 & 1 & 0.4609 & 0.2862 & 0.6501 \\ 0.4196 & 1 & 0.4609 & 0.2862 & 0.1468 \\ 0.3913 & 0 & 0.5144 & 0.1579 & 1 \end{bmatrix} \\ C_{0.79} &= \begin{bmatrix} 0.4340 & 0 & 0.4609 & 0.2862 & 0.4018 \\ 0.4634 & 1 & 0.4609 & 0.2862 & 0.6501 \\ 0.3114 & 1 & 0.3008 & 0.1289 & 0.0775 \end{bmatrix} \\ C_{0.97} &= \begin{bmatrix} 0.3373 & 0 & 0.4101 & 0.3775 & 0.4785 \\ 0.4634 & 1 & 0.4609 & 0.2862 & 0.6501 \end{bmatrix} \end{split}$$

The C matrixes that mentioned below are the result of cluster centroid for each applied radius. The $C_{0.72}$ matrix points the matrix of the acquired cluster centroid with radius 0.72. The first row on $C_{0.72}$ matrix shows the first cluster centroid, the second row shows the second cluster centroid, the third row shows the third cluster centroid, and the fourth row shows the fourth cluster centroid.

Furthermore, the application of Minkowski Chebisev combination distance will resulted in 3 classification for each radius; by using r = 1.12, 4 clusters will be achieved; by using r = 1.31, 3 clusters will be achieved; and by using r = 1.6, 2 clusters will be achieved. The achieved cluster centroid are described as follows:

| | Г 0 | | | | 0.4018ך |
|---------------------|---------|---|--------|--------|--------------------|
| c – | 0.5900 | 1 | 0.4609 | 0.1289 | 0.5900 |
| C _{1.12} – | 0.5092 | 0 | 1 | 1 | $0.5900 \\ 0.6196$ |
| | L0.7894 | 0 | 0.7571 | 0.2862 | 0.2439 |

| | 0 | 0 | 0.4609 | 0.1289 | 0.4018 0.5900 0.6196 |
|---------------|---------|---|--------|------------------|----------------------------|
| $C_{1.31} =$ | 0.5900 | 1 | 0.4609 | 0.1289 | 0.5900 |
| | L0.5092 | 0 | 1 | 1 | 0.6196 |
| c –[| 0 | 0 | 0.4609 | 0.1289 0.4785 | ן0.4018 |
| $c_{1.6} - [$ | 0.7508 | 1 | 0.6501 | 0.4785 | 0.7132 |

The C matrixes that mentioned below are the output of cluster centroid for each applied radius. The $C_{1,12}$ matrix points the matrix of the achieved cluster centroid with radius 0.72. The first row, the second row, the third row, and the fourth row on $C_{0.72}$ matrix shows the first, second, third, and fourth cluster centroid respectively.

Afterwards, the achieved number of clusters are evaluated by applying Partition Coefficient value. Then, the result of the Partition value for FSC method with the application of Hamming distance and Minkowski Chebisev combination distance is compared. The result comparison is shown in figure 1.

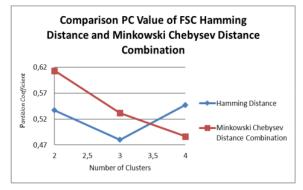

Figure 1 Partition Coefficient Value Comparson of Fuzzy Subtractive Clustering

Based on figure 1, the achieved Partition Coefficient value for Hamming distance application are lower than the Partition Coefficient value for Minkowski Chebisev combination distance application. The Partition Coefficient value from the Hamming distance for 2 achieved clusters is 0.5369, for 3 achieved clusters is 0.4801, and for 4 achieved clusters is 0.5473. At the same time, the Partition Coefficient value from Minkowski Chebisev combination distance for 2 achieved clusters, and 4 achieved clusters are 0.6135, 0.5319, and 0.4867 respectively.

5. CONCLUSION

In this research, the clustering method which being used is Fuzzy Subtractive Clustering with the application of Hamming distance and Minkowski Chebisev combination distance. Then, the Partition Coefficient value which measured from the Fuzzy Subtractive Clustering method with 2 mentioned distance parameter will be compared. Generally, the Minkowski Chebisev combination distance application is resulting in Partition Coefficient value which are better than the Partition Coefficient value acquired from the application of Hamming distance. This conclusion is concluded because of the Partition Coefficient value resulted from the application of Minkowski Chebisev combination distance are generally higher than the Partition Coefficient value achieved from the Hamming distance application.
